# Mass Spectroscopy

How do we know isotopes exist?

Why?

When John Dalton proposed the first formal atomic theory, he stated "Atoms of the same element are identical." Today we know that is not true—many elements contain several different isotopes, or atoms that differ in mass. Mass spectroscopy is the principle technique used to study isotopes. It is used to both "count" and "weigh" atoms in a sample, just not in the traditional sense.

Model 1 – Sorting by Mass

1. According to Model 1 what four processes occur inside a mass spectrometer?

2. Consider where the sample is introduced into the mass spectrometer in Model 1. Which one of the four processes from Question 1 is the first process?

3. Match the four processes from Question 1 to the following descriptions.

   _____ Ions collide with a metal plate. Electrons are transferred from the metal to the ion, producing a current and thus a signal to a computer.

   _____ Ions are attracted to the negative side of an electromagnetic field causing separation of the mixture based on mass and charge.

   _____ Electrons are knocked off sample particles to form (mostly) +1 ions.

   _____ Ions move through a series of charged plates to form a narrow beam of high speed particles with equal kinetic energy.

4. When a sample is injected into the mass spectrometer, do the atoms or molecules turn into positive or negative ions? Justify your answer with at least two pieces of evidence from Model 1.

5. According to Model 1, what causes the sample mixture to become separated?

The key to mass spectrometry is that all of the particles go into the deflection chamber with the same kinetic energy. They do not, however, have the same **mass/charge ratio (m/z)**. Although most of the ions formed are +1 ions, their masses are different. Therefore, the amount of deflection they experience by the electromagnet is different. The strength of the electromagnet can be varied so only particles with a particular mass/charge ratio can make it to the detector. Other particles collide with the metallic sides of the instrument, are neutralized, and then removed by the vacuum pump. The machine is calibrated using carbon-12 isotopes which are, by definition, exactly 12 amu (12.0000000…amu).
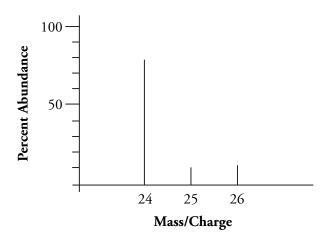

6. Consider the following ions formed in a mass spectrometer. Rank the ions in terms of their degree of deflection by the electromagnet from least to greatest. Greater deflection means a tighter turn towards the negative pole of the electromagnet. Make sure all group members are able to explain the ranking.

$$^{19}F^{1+} \qquad ^{16}O^{1+} \qquad ^{17}O^{1+}$$

7. Why is it necessary to have the mass spectrometer chamber under vacuum (very low pressure) for it to work properly?

Model 2 – A Mass Spectrum

8. Model 2 is the mass spectrum that resulted from the experiment in Model 1.

    a. What is the mass number of the most common isotope of magnesium?

    b. What is the percent abundance of the most common isotope of magnesium?

9. The average atomic mass of an element can be estimated from data on a mass spectrum.

    a. Calculate the average atomic mass of magnesium using data from Model 2. *Hint:* You will not get the correct answer if you add 24, 25 and 26 and divide by 3.

    b. Give two reasons why your calculated value in part *a* is only an estimate of the average atomic mass of the element magnesium.

10. The table below provides mass number and percent abundance information for the element lead. Draw a mass spectrum for lead. (You can assume only +1 ions of lead are formed.)

^{204}Pb	1.4%
^{206}Pb	24.1
^{207}Pb	22.1
^{208}Pb	52.4

The mass spectra you have been looking at in this activity used percent abundance on the *y*-axis. Typically, however, the spectra use relative intensity. The ions from the sample are sorted by mass/charge ratio by the mass spectrometer. The ion that hits the detector most often is assigned a relative intensity of 100. The other ions are given proportional relative intensities based on their abundance in the sample. An example of magnesium's mass spectrum shown both ways is given below.

11. Consider the two mass spectra in the *Read This!* box.

    a. The sum of all percent abundances for magnesium is equal to 100. Explain why this is reasonable.

   b. The sum of all relative intensities for magnesium does not equal 100. Explain why this is reasonable.

12. Imagine that the relative intensities on the mass spectra in the *Read This!* box represent the number of particles in a sample.

    a. Theoretically, how many magnesium ions were detected by the mass spectrometer?

    b. What percentage of the ions were ^{24}Mg ions? Show mathematical work to support your answer.

    c. Show mathematically how a computer might translate the 13 peak in the relative intensity graph to 10% for the percent abundance graph.

The process of ionization inside of a mass spectrometer is quite violent. There are several methods of ionization used in industry, but many of them remove electrons from the atoms or molecules by high energy particle bombardment. In other words, the electrons are knocked off the atoms or molecules by high speed particles colliding with them. Occasionally this process will break apart a molecule. This is called **fragmentation**. The pieces are analyzed by the mass spectrometer along with the whole molecules.

13. The following information was gathered by mass spectroscopy for the element fluorine. Fluorine has only one natural isotope, but it does form diatomic molecules naturally. Propose an explanation for the two lines on fluorine's mass spectrum.

14. The element chlorine has two natural isotopes: ^{35}Cl (76% abundance) and ^{37}Cl (24% abundance). The mass spectrum of chlorine has five lines.

    a. Three of the lines in the mass spectrum are from diatomic molecules of chlorine. List the three possible combinations of the two isotopes and their total mass number.

    b. Explain the remaining two lines in the spectrum.

    c. Draw a mass spectrum that would result from diatomic chlorine. Include the mass/charge number and estimate the relative abundance of each ion. (Assume only +1 ions are formed.) Although the heights of the peaks are difficult to predict you should be able to determine which will be taller or shorter based on the abundance of each chlorine isotope.

Extension Questions

Model 3 – Successive Ionization Energies

| 1st Ionization	$Mg\,(g)\ +\ energy\ \rightarrow\ Mg^{1+}(g)\ +\ e^-$
2nd Ionization	$Mg^+(g)\ +\ energy\ \rightarrow\ Mg^{2+}(g)\ +\ e^-$

15. List two ways that the first ionization and second ionization of an atom are similar.

16. List two ways that the first ionization and second ionization of an atom are different.

17. Occasionally a particle introduced into a mass spectrometer is ionized twice, causing a 2^+ ion to be formed. Consider the 1st and 2nd ionization energies of several atoms in the table below.

Element	1st Ionization Energy (kJ/mole)	2nd Ionization Energy (kJ/mole)
Magnesium	738	1451
Chlorine	1251	2298
Xenon	1170	2046
Oxygen	1314	3388

a. How do 1st ionization and 2nd ionization energies usually compare for an atom?

b. Propose a reason why very few 2^+ ions are formed in a mass spectrometer.

c. If 2^+ ions of magnesium were formed in the mass spectrometer chamber illustrated in Model 1, would they be deflected more or less than the 1^+ ions by the electromagnet?

18. What would the mass spectrum of magnesium look like if a small portion of atoms were ionized to 2^+ ions?

19. Mass spectroscopy is also used to study large organic molecules. When a sample of a pure compound is analyzed in the instrument, some of the molecules get ionized whole (molecular ions), while some are fragmented and ionized. The fragmentation occurs in predictable patterns allowing scientists to propose chemical structures for unknown substances. Consider the mass spectrum of pentane ($CH_3CH_2CH_2CH_2CH_3$) shown below.

a. Match the molecular ion and fragment ions below to each of the lettered peak clusters in the mass spectrum.

$CH_3CH_2CH_2CH_2CH_3^+$
$CH_3CH_2CH_2CH_2^+$
$CH_3CH_2CH_2^+$
$CH_3CH_2^+$
CH_3^+

b. Peak cluster A has a small peak at 14. What may have fallen of the CH_3^+ ion to form this peak?
