### Section Objectives

**Section 39.1** 1 session, 1/2 block

1. Outline the steps of Koch’s postulates.
2. Describe how pathogens are transmitted.
3. Explain what causes the symptoms of a disease.

**Section 39.2** 2 sessions, 1/2 block

4. Identify the cells, tissues, and organs that make up the immune system.
5. Compare innate and acquired immune responses.
6. Distinguish between antibody and cellular immunity.

### National Science Standards

**UCP.1, UCP.2, UCP.5; A.1, A.2; C.1, C.4; F.1, F.5; G.1–3**

### State/Local Standards

### Key to Teaching Strategies

- **L1** Level 1 activities should be appropriate for students with learning difficulties.
- **L2** Level 2 activities should be within the ability range of all students.
- **L3** Level 3 activities are designed for above-average students.
- **ELL** ELL activities should be within the ability range of English Language Learners.
- **COOP LEARN** Cooperative Learning activities are designed for small group work.
Reproducible Masters and Transparencies

Short on Time?

BIO DIGEST The BioDigest at the end of this unit can be used as a(n):
• preview to introduce important unit concepts.
• overview if time does not permit teaching the entire chapter.
• review of key unit concepts.

Understanding the Photo
A lymphocyte is a type of white blood cell that defends the body against foreign substances. Lymphocytes include B cells and T cells which are responsible for destroying bacteria as well as viruses and fungi. These cells can also be involved in autoimmune diseases such as rheumatoid arthritis and lupus.

What You'll Learn

I You will describe how infections are transmitted and what causes the symptoms of diseases.
I You will explain the various types of innate and acquired immune responses.
I You will compare antibody and cellular immunity.

Why It's Important
Your body constantly faces attack from disease-causing organisms. A knowledge of your immune system will help you understand how your body defends itself and works to maintain homeostasis.

Understanding the Photo
This color-enhanced lymphocyte, a type of white blood cell produced by the immune system, is attacking the rod-shaped bacteria that have invaded the body.

Activity Ask how many students had at least one cold last year. Colds are caused by over 80 different viruses. Ask the students to describe what happened when the viruses attached to the cells of their nasal cavity. Use this to review the life cycle of a virus covered in Chapter 18 on pages 474–501. The viruses attach to the epithelial cells of the nasal cavity and inject their nucleic acid into the cell. The epithelial cell’s metabolic machinery makes viral nucleic acids and viral proteins. The virus particles are assembled, and the host cells open and release new viral particles to infect more cells.
**The Nature of Disease**

**SECTION PREVIEW**

**Objectives**
- Outline the steps of Koch’s postulates.
- Describe how pathogens are transmitted.
- Explain what causes the symptoms of a disease.

**Review Vocabulary**
- virus: a disease-causing, nonliving particle composed of an inner core of nucleic acids surrounded by a capsid; replicates inside a living cell (p. 475)

**New Vocabulary**
- pathogen
- infectious disease
- Koch’s postulates
- endemic disease
- epidemic
- antibiotic

**Disease**

Make the following Foldable to help you answer questions about disease.

**STEP 1** Fold a vertical sheet of notebook paper from side to side.

**STEP 2** Cut along every fifth line of only the top layer to form tabs.

**STEP 3** Label the tabs with one question that relates to each of the red heads in the section. For example, “What causes disease?”

**Answer Questions**

As you read Section 39.1, fill in your answers to the questions about disease beneath the appropriate tabs.

---

**What is an infectious disease?**

The cold virus causes a disease—a change that disrupts the homeostasis in the body. Disease-producing agents such as bacteria, protozoans, fungi, viruses, and other parasites are called pathogens. The main sources of pathogens are soil, contaminated water, and infected animals, including other people.

Not all microorganisms are pathogenic. In fact, the presence of some microorganisms in your body is beneficial. At birth, microorganisms establish themselves on your skin and in your upper respiratory system, lower urinary and reproductive tracts, and lower intestinal tract. **Figure 39.1** shows some common bacteria that live on your skin.

---

**Figure 39.1**

These bacteria establish a more-or-less permanent residence in or on your skin, but do not cause disease under normal conditions.
These microorganisms have a symbiotic relationship with your body. Microorganisms that colonize the body help maintain equilibrium within the body by keeping harmful bacteria and other microorganisms from growing. If conditions change and the beneficial organisms are eliminated, pathogens can establish themselves and cause infection and disease. If the beneficial organisms enter areas of the body where they are not normally found or if a person becomes weakened or injured, these formerly harmless organisms can become potential pathogens.

Any disease caused by the presence of pathogens in the body is called an infectious (ihn FEK shus) disease. Table 39.1 lists some of the infectious diseases that occur in humans.

### Determining What Causes a Disease

One of the first problems scientists face when studying a disease is finding out what causes the disease. Not all diseases are caused by pathogens. Some disorders are inherited, such as hemophilia (hee muh FIH lee uh), which is caused by a recessive allele on the X chromosome, and sickle-cell anemia. Others, such as osteoarthritis (ahs tee oh ar THRItus), may be caused by wear and tear on the body as it ages. Some diseases, such as cirrhosis (suh ROH sihs), are caused by exposure to chemicals or toxins such as alcohol that destroy liver cells. Other diseases can be caused by malnutrition. Scurvy, which results in poor wound healing, swollen gums, and loosening of teeth, is caused by a deficiency of vitamin C. Pathogens cause infectious diseases and some cancers. In order to determine which pathogen causes a specific disease, scientists follow a standard set of procedures.

### First pathogen identified

The first proof that pathogens actually cause disease came from the work of Robert Koch (KAIKH) in 1876. Koch, a German physician, was looking for the cause of anthrax, a deadly disease that affects mainly
cattle and sheep but can also occur in humans. Koch discovered a rod-shaped bacterium in the blood of cattle that had died of anthrax. He cultured the bacteria on nutrients and then injected samples of the culture into healthy animals. When these animals became sick and died, Koch isolated the bacteria in their blood and compared them with the bacteria he had originally isolated from anthrax victims. He found that the two sets of blood cultures contained the same bacteria.

A procedure to establish the cause of a disease
Koch established experimental steps, shown in **Figure 39.2**, for directly relating a specific pathogen to a specific disease. These steps, first published in 1884, are known today as **Koch’s postulates**:

1. The pathogen must be found in the host in every case of the disease.
2. The pathogen must be isolated from the host and grown in a pure culture—that is, a culture containing no other organisms.
3. When the pathogen from the pure culture is placed in a healthy host, it must cause the disease.
4. The pathogen must be isolated from the new host and be shown to be the original pathogen.

**Exceptions to Koch’s postulates**
Although Koch’s postulates are useful in determining the cause of most diseases, some exceptions exist. Some organisms, such as the pathogenic bacterium that causes the sexually transmitted disease syphilis (*Sífí lus*), have never been grown on an artificial medium. Viral pathogens also cannot be cultured this way because they multiply only within cells. As a result, living tissue must be used as a culture medium for viruses.

Brainstorming
Have students discuss the importance of each step of Koch’s postulates and how skipping any of them would affect the results of a search for the pathogen that causes a particular disease.

**Discussion**
Explain the term *plague* and ask why some people survived plagues while many others perished. A plague is an epidemic disease that results in a high number of deaths. Students may suggest that people in better health may have been more resistant to infection or possessed some unusual trait that prevented them from succumbing to infection. Accept all logical responses. Initiate a general discussion about the body’s defenses to disease.
The Spread of Infectious Diseases

For a disease to continue and spread, there must be a continual source of the disease organisms. This source can be either a living organism or an inanimate object on which the pathogen can survive.

Reservoirs of pathogens

The main source of human disease pathogens is the human body itself. In fact, the body can be a reservoir of disease-causing organisms. People may transmit pathogens directly or indirectly to other people. Sometimes, people can harbor pathogens without exhibiting any signs of the illness and unknowingly transmit the pathogens to others. These people are called carriers and are a significant reservoir of infectious diseases.

Other people may unknowingly pass on a disease during its first stage, before they begin to experience symptoms. This symptom-free period, while the pathogens are multiplying within the body, is called an incubation period. Humans can unknowingly pass on the pathogens that cause colds, streptococcal (streptuh KAHH kul) throat infections, and sexually transmitted diseases (STDs) such as gonorrhea (gah nuh REE uh) and AIDS during the incubation periods of these diseases.

Animals are other living reservoirs of microorganisms that cause disease in humans. For example, some types of influenza, commonly known as the flu, rabies, and Lyme disease are transmitted to humans from animals.

The major nonliving reservoirs of infectious diseases are soil and water. Soil harbors pathogens such as fungi and the bacterium that causes botulism, a type of food poisoning. Water contaminated by feces of humans and other animals is a reservoir for several pathogens, especially those responsible for intestinal diseases.

Figure 39.3
Diseases can be transmitted to humans from reservoirs in various ways.

A Common inanimate objects such as this glass of juice may harbor and transmit pathogens.

B Airborne transmission by droplets of water or dust spreads pathogens.

C Insects and other arthropods are the most common pathogen vectors.

Project

Antimicrobial Drugs Have students research the difference between drugs that are bactericidal and those that are bacteriostatic. Have students explain the different mechanisms by which these drugs help eliminate bacteria from the body. Bactericidal drugs kill bacteria, bacteriostatic drugs prevent bacteria from growing. These drugs usually work by inhibiting an essential process from occurring such as cell wall synthesis, protein synthesis, or nucleic acid synthesis.

Disease Prevention: Interpersonal Students who have part-time jobs or are looking for a career that includes disease prevention can find out what measures are used to prevent the spread of disease. Examples of work places in which disease prevention is practiced include plant nurseries, doctors' offices, dentists' offices, veterinarians' offices, hospitals, and the food industry.
Transmission of disease

Pathogens can be transmitted to a host from reservoirs in four main ways: by direct contact, by an object, through the air, or by an intermediate organism called a vector. Figure 39.3 illustrates several routes of transmission.

The common cold, influenza, and STDs are spread by direct contact. STDs, such as genital herpes and the virus that causes AIDS, are usually transmitted by the exchange of body fluids, especially during sexual intercourse.

Bacteria and other microorganisms can be present on nonliving objects such as money, toys, or towels. Transmission occurs when people unknowingly handle contaminated objects. This type of transmission can be prevented by thoroughly cleaning objects such as eating utensils and countertops that can harbor pathogens, and by washing your hands often throughout each day.

Airborne transmission of a disease can occur when a person coughs or sneezes, spreading pathogens contained in droplets of mucus into the air. Streptococcus, the bacterium that causes strep throat infections, and the virus that causes measles are two examples of disease-causing organisms that can be spread through the air.

Diseases transmitted by vectors are most commonly spread by insects and arthropods. Diseases such as malaria and the West Nile virus are transmitted by mosquitoes. Lyme disease and Rocky Mountain spotted fever are diseases that are transmitted by ticks. The bubonic plague—a disease that swept through Europe in the fourteenth century, killing up to one-quarter of the population—was caused by a bacterium that was transmitted from infected rats to humans by fleas. Flies also are significant vectors of disease. They transmit pathogens when they land on infected materials, such as animal wastes, and then land on fresh food that is eaten by humans. A current international concern is the intentional spreading of disease organisms such as anthrax spores, as occurred in the fall of 2001 in the United States through contaminated mail. To learn more about how diseases are spread, refer to the Problem-Solving Lab here and the MiniLab on the next page.

Problem-Solving Lab 39.1

**Design an Experiment**

How does the herpes simplex virus spread? Herpes (HER peez) simplex virus, which causes cold sores, infects a person for life, occasionally reproducing and then spreading to other cells in the body of its host. Scientists have been interested for a long time in how the herpes virus actually enters a cell.

**Solve the Problem**

Scientists have found that the herpes virus infects a cell in one of two possible ways. It may latch onto a cell receptor with its own glycoprotein spike, or it may use this spike to grab a growth factor molecule that latches onto the receptor, as shown in the diagram.

**Thinking Critically**

**Experiment** Design an experiment to determine the method by which the herpes virus enters a cell.

**Purpose**

Students will design an experiment to determine how a virus enters a cell.

**Process Skills**

observe and infer, formulate models

**Teaching Strategies**

Ask students to include a control setup in their procedures.

**Thinking Critically**

Student answers will vary. One experiment might be to remove the growth factor from the cell to see if the virus can still get in. Another possibility would be to remove the receptor sites from the cell or to remove the glycoprotein spikes from the virus to see if the virus can still get in.

**Assessment**

**Portfolio** Ask students to write a summary of the lab. Have them include the summaries of their experimental designs in their portfolios. Use the Performance Task Assessment List for Lab Report in PASC, p. 119.

**Health Careers**

Encourage students who are interested in health-related careers to set up an interview with members of the local Health Department to learn more about their roles in safeguarding community health.
MiniLab 39.1

Purpose
Students will examine how microbes are transmitted by direct contact.

Process Skills
use controls; collect, organize, and interpret data; experiment; analyze

Teaching Strategies
Point out that the brown area under the apple skin may be caused by bacteria.

Safety Precautions
Have students wash their hands after handling the rotting apples. All apples should be destroyed following the MiniLab.

Expected Results
Apples 2 and 3 will develop brown spots and decay. Apple 1 will show little or no change. Apple 4 will show little or no change, because the alcohol may have inhibited the decay.

Analysis
1. Explain What was the purpose of the apple in bag 1?
2. Describe What happened to the rest of the apples?
3. Infer Why is it important to clean a wound with disinfectant?

Assessment
Performance Ask students to write a summary of the lab, including their results. Have them place their summaries and their answers to the Analysis questions in their journals. Use the Performance Task Assessment List for Lab Report in PASC, p. 119.

Experiment

Testing How Diseases Are Spread
Microorganisms cannot travel over long distances by themselves. Unless they are somehow transferred from one animal or plant to another, infections will not spread. One method of transmission is by direct contact with an infected animal or plant.

Procedure
1. Label four plastic bags 1 to 4.
2. Put a fresh apple in bag 1 and seal the bag.
3. Rub a rotting apple over the entire surface of the remaining three apples. The rotting apple is your source of pathogens. CAUTION: Make sure to wash your hands with soap and water after handling the rotting apple.
4. Put one of the apples in bag 2.
5. Put one of the apples in bag 3 and drop the bag to the floor from a height of about 2 m.
6. Use a cotton ball to spread alcohol over the last apple. Let the apple air-dry and then place it in bag 4.
7. Store all of the bags in a dark place for one week.
8. Without opening the sealed bags, compare the apples and record your observations. CAUTION: Give all apples to your teacher for proper disposal.

Analysis

1. What causes the symptoms of a disease?
   When a pathogen invades your body, it encounters your immune system, which consists of individual cells, tissues, and organs that work together to protect the body against organisms that may cause infection or disease. If the pathogen overcomes the defenses of your immune system, it can metabolize and multiply, causing damage to the tissues it has invaded, and even killing host cells.

2. Damage to the host by viruses and bacteria
   You already know that viruses cause damage by taking over a host cell's genetic and metabolic machinery. Many viruses also cause the eventual death of the cells they invade.
   Most of the damage done to host cells by bacteria is inflicted by toxins. Toxins are poisonous substances that are sometimes produced by microorganisms. These poisons are transported by the blood and can cause serious and sometimes fatal effects. Toxins can inhibit protein synthesis in the host cell, destroy blood cells and blood vessels, produce fever, or cause spasms by disrupting the nervous system.

Wartime Medicines
Have students who need an additional challenge conduct research to find examples of medicines developed during wartime that have become important in treating civilians.

Ask them to identify the reason the medicine was developed and explain what disease(s) it has been used to treat.
For example, the toxin produced by tetanus bacteria affects nerve cells and produces uncontrollable muscle contractions. If the condition is left untreated, paralysis and death occur. Tetanus bacteria are normally present in soil, and as Figure 39.4 illustrates, a soldier could become infected with tetanus as a result of wounds received on the battlefield. If dirt transfers the bacteria into a deep wound on the body, the bacteria begin to produce the toxin in the wounded area. A small amount of this toxin, about the same amount as the ink used to make a period on this page, could kill 30 people.

Patterns of Diseases

The outbreak in 2003 of severe acute respiratory syndrome (SARS) spread to more than two dozen countries within a few months. Identifying a pathogen, its method of transmission, and the geographic distribution of the disease it causes are major concerns of government health departments. The Centers for Disease Control and Prevention, the central source of disease information in the United States, publishes a weekly report about the incidence of specific diseases.

Some diseases, such as typhoid fever, occur only occasionally in the United States. These periodic outbreaks often occur because someone traveling in a foreign country has brought the disease back home. On the other hand, many diseases are constantly present in the population. Such a disease is called an endemic disease. The common cold is an endemic disease.

Sometimes, an epidemic breaks out. An epidemic occurs when many people in a given area are afflicted with the same disease at about the same time. Influenza is a disease that often achieves epidemic status, sometimes spreading to many parts of the world. During the early 1950s, a polio epidemic spread across the United States. Victims of this disease were paralyzed or died when the polio virus attacked the nerve cells of the brain and spinal cord. Many survived only after being placed in an iron lung—a machine that allowed the patient to continue to breathe, as shown in Figure 39.5. You can learn more about emerging and re-emerging diseases in the BioLab at the end of the chapter.

Treating Diseases

A person who becomes sick often can be treated with medicinal drugs, such as antibiotics. An antibiotic is a substance produced by a microorganism that, in small amounts, will kill or inhibit the growth and reproduction of other microorganisms, especially bacteria. Antibiotics are produced naturally by various species of bacteria and fungi. Although antibiotics can be used to cure some bacterial infections, antibiotics do not have an effect on viruses.

Word Origin

epidemic from the Greek words epi, meaning "upon," and demos, meaning "people"; An epidemic is a disease found among many people in an area.

Figure 39.5

During the early 1950s polio epidemic, many patients were placed in iron-lung machines like those shown here.

Caption Question Answer

Figure 39.4 (page 1028) The battlefield contains wounded men that have dirt in their wounds. Tetanus bacteria, which are found in soil, produce toxins when they are found in deep wounds.

Discussion

Elicit from students why addicts who share needles when taking drugs often spread diseases to each other. The needles are not sterile. Pathogens present on the needles themselves or present in fluids (including blood) contained in the needles are easily passed from one person to the next. Explain to students that this process is an example of transmission by an object.

Enrichment

Discuss with students how the development of a vaccine for tetanus has reduced the occurrence of this disease in developed nations. Explain the need for periodic boosters to maintain effectiveness of the vaccine.

Brainstorming

Ask students to speculate why antibiotics are sometimes given during a viral infection if they are ineffective against viruses. to prevent secondary bacterial infections.
With the continued use of antibiotics, bacteria can become resistant to the drugs. That means the drugs become ineffective. Penicillin, an antibiotic produced by a fungus, was used for the first time in the 1940s and is still one of the most effective antibiotics known. However, penicillin has now been in use for more than 50 years, and more and more types of bacteria have evolved that are resistant to it. Bacteria that are resistant to penicillin produce an enzyme that breaks down this antibiotic. Examples of penicillin-resistant bacteria include *Streptococcus pneumoniae*, shown in Figure 39.6, and the organism that causes the STD gonorrhea. The resistance of *Streptococcus pneumoniae* to penicillin is a problem because penicillin is the primary drug used to treat pneumonia, ear infections, and meningitis, all of which can be caused by this organism.

The use of antibiotics is only one way to fight infections. Your body also has its own built-in defense system—the immune system—that works to keep you healthy.

### Understanding Main Ideas

1. Outline and explain the steps of Koch's postulates.
2. What are the major reservoirs of pathogens?
3. List the different ways in which pathogens are transmitted.
4. How do pathogens, such as some bacteria and viruses, cause disease symptoms?

### Thinking Critically

5. Sometimes patients contract a secondary infection while in the hospital. What possible ways could a disease be transmitted to a hospital patient?

6. **Experiment** Design an experiment that could determine whether a recently identified bacterium causes a type of pneumonia. For more help, refer to **Experiment** in the **Skill Handbook**.

### Section Assessment

1. The pathogen must be found in the host in every case of the disease. The pathogen must be isolated from the host and grown in pure culture. When the pathogen from the pure culture is placed in a healthy host, it must cause the disease. The pathogen must be isolated from the new host and be shown to be the original pathogen.
2. Humans, animals, soil, and water
3. Direct contact, through contaminated air, water, or inanimate object, or by a vector
4. Disease symptoms are often caused by bacterial toxins or death of body tissue
5. By direct contact with employees or patients, through contaminated objects, or by airborne transmission
6. Grow suspected organisms in a pure culture, then inject them into another host. If that host develops the same disease, the organisms probably caused it. To be sure, isolate the organisms and compare with the original organisms.
Defense Against Infectious Diseases

Using an Analogy  You can’t see it, but a war is going on around these teenagers. In fact, the same sort of war is occurring around you. Millions of unseen enemies are present everywhere—in the air, on the ground, and even on your clothes. Defenders ready to protect you from the onset of attack are inside your body. **Infer** How does your body save you from the microscopic foes that cause infectious diseases? How do the body’s defenses protect you from these unseen enemies?

**Innate Immunity**

Your body produces a variety of white blood cells that defend it against invasion by pathogens that are constantly bombarding you. No matter what pathogens are present, your immune system is always ready. The body’s earliest lines of defense against any and all pathogens make up your nonspecific, **innate immunity**.

**Skin and body secretions**

When a potential pathogen contacts your body, often the first barrier it must penetrate is your skin. Like the walls of a castle, intact skin is a formidable physical barrier to the entrance of microorganisms.

In addition to the skin, pathogens also encounter your body’s secretions of mucus, oil, sweat, tears, and saliva. The main function of mucus is to prevent various areas of the body from drying out. Because mucus is slightly viscous (thick), it also traps many microorganisms and other foreign substances that enter the respiratory and digestive tracts. Mucus is continually swallowed and passed to the stomach, where acidic gastric juice destroys most bacteria and their toxins. Sweat, tears, and saliva all contain the enzyme lysozyme, which is capable of breaking down the cell walls of some bacteria.

**New Vocabulary**

innate immunity
phagocyte
macrophage
pus
interferon
acquired immunity
tissue fluid
lymph
lymph node
lymphocyte
T cell
B cell
vaccine
Inflammation of body tissues

If a pathogen manages to get past the skin and body secretions, your body has several other nonspecific defense mechanisms that can destroy the invader and restore homeostasis. Think about what happens when you get a splinter. If bacteria or other pathogens enter and damage body tissues, inflammation (ihn fluh MAY shun) results. Inflammation is characterized by four symptoms—redness, swelling, pain, and heat. As Figure 39.7 shows, inflammation begins when damaged tissue cells called mast cells, and white blood cells called basophils release histamine (HIHS tuh meen). Histamine causes blood vessels in the injured area to dilate, which makes them more permeable to tissue fluid. These dilated blood vessels cause the redness of an inflamed area. Fluid that leaks from the vessels into the injured tissue helps the body destroy toxic agents and restore homeostasis. This increase in tissue fluid causes swelling and pain, and may also cause a local temperature increase. Inflammation can occur as a reaction to other types of injury as well as infections. Physical force, chemical substances, extreme temperatures, and radiation may also inflame body tissues.

Phagocytosis of pathogens

Pathogens that enter your body may encounter cells that carry on phagocytosis. Recall that phagocytosis occurs when a cell engulfs a particle. Phagocytes (FA guh sites) are white blood cells that destroy pathogens by surrounding and engulfing them. Phagocytes include monocytes, which develop into macrophages, neutrophils, and eosinophils. Macrophages are present in body tissues. The other types of phagocytes circulate in the blood.

Macroagathes are white blood cells that provide the first defense against pathogens that have managed to enter the tissues. Macrophages, shown in Figure 39.8, are found in the tissues of the body. They are sometimes called giant scavengers, or big eaters, because of the manner in which they engulf pathogens or

Figure 39.7
When tissues become inflamed, histamine release causes blood vessels to dilate (A). Tissue fluid leaks out of the vessels into the injured area, causing swelling (B).
damaged cells. Lysosomal enzymes inside the macrophage digest the particles it has engulfed.

If the infection is not stopped by the tissue macrophages, another type of phagocyte, called a neutrophil, is attracted to the site. They also destroy pathogens by engulfing and digesting them.

If the infection is not stopped by tissue macrophages and neutrophils, there is a third method of defense. A different type of phagocyte begins to arrive on the scene. Monocytes are small, immature macrophages that circulate in the bloodstream. These cells squeeze through blood vessel walls to move into the infected area. Once they reach the site of the infection they mature and are now called macrophages. They then begin consuming pathogens and dead neutrophils by phagocytosis. Once the infection is over, some monocytes mature into tissue macrophages that remain in the area, prepared to fend off a new infection.

After a macrophage has destroyed large numbers of pathogens, dead neutrophils, and damaged tissue cells, it eventually dies. After a few days, infected tissue harbors a collection of live and dead white blood cells, multiplying and dead pathogens, and body fluids called pus. Pus formation usually continues until the infection subsides. Eventually, the pus is cleared away by macrophages.

Which white blood cells are involved in the body’s defense against pathogens? Find out by looking at Figure 39.9 on the following page and by carrying out the MiniLab on page 1035 to observe the different types of white blood cells.

Protective proteins

When an infection is caused by a virus, your body faces a problem. Phagocytes alone cannot destroy viruses. Recall that a virus multiplies within a host cell. A phagocyte that engulfs a virus will itself be destroyed if the virus multiplies within it. One way your body can counteract viral infections is with interferons. Interferons are proteins that protect cells from viruses. Interferons are host-cell specific. This means that human interferons will protect human cells from viruses but cannot protect cells of other species from the same virus.

Reinforcement

Have students orally make an analogy between the reaction of the immune system and a battle scene. Ask them who or what might represent the skin, tissue macrophages, neutrophils, and monocytes.

Inquiry

The Common Cold

Have students research and create a chart that shows the different types of viruses that can cause a cold. Have them answer the question: Why won’t a single vaccine combat the common cold? A single vaccine cannot be effective against all of the different viruses that can cause a cold.

Assessment

Knowledge

Ask students to describe similarities between a macrophage and an amoeba. Both engulf particles by phagocytosis.

L2

2. Using a cotton swab, transfer some of the bacterial culture to the agar plate.
3. Spread the culture evenly over the surface of the agar plate using the cotton swab.
4. Dip the forceps into alcohol. Let them to air dry without touching any surface.
5. Use the forceps to transfer two antibiotic disks into each of three sections of the plate. Transfer two untreated disks to the fourth section of the plate. Label the bottom with the type of antibiotic used in each section.
6. Tape the plates closed and incubate for 48 hours at 37°C.
7. Look for regions of inhibition.

Analysis

1. Why were untreated disks placed in one section? This section was the control.
2. Did any of the antibiotics inhibit the growth of the bacteria? Answers will vary.
Purpose

Students visualize the various types of white blood cells and their role in the immune system.

Teaching Strategies

- Review this page with students before and after completing MiniLab 39.2.
- Have students prepare a table of the white blood cells that compares their characteristics, functions, and where they are found.
- Have students discuss what would happen to the numbers of white blood cells during an infection. The number of white blood cells per milliliter of blood increases during an infection.

Visual Learning

Using a microscope projector, point out the various types of white blood cells on a blood smear slide.

Critical Thinking

Mature tissue macrophages are not found in the blood but out in the body tissues. Immature macrophages, called monocytes, are found in the bloodstream.

Immune Responses

Figure 39.9
White blood cells play a major role in protecting your body against disease. Many of these cells leave the bloodstream to fight disease organisms in the tissues. Critical Thinking Why would you not expect to see tissue macrophages in a sample of blood cells?

A Innate immune response
Macrophages are large, phagocytic white blood cells found in the tissues. They are the first to arrive at the site of an infection. Basophils, found in the blood, are not phagocytic. They are filled with granules that release histamine at an infection site. Eosinophils are also granular and also play a role in inflammation.

B Second wave of defenders A neutrophil (above) is a phagocytic white blood cell with a nucleus that has several lobes.

C Continued defense After moving from the blood into an infected area, monocytes (above) mature into macrophages. Monocytes are two to three times larger than other blood cells and have large nuclei. They replenish the supply of tissue macrophages following an infection.

D Acquired immune response Lymphocytes (above) are cells with nuclei that nearly fill the cell. They include B cells and T cells and are involved in developing immunity to specific pathogens. Lymphocytes are found in the blood, spleen, thymus, lymph nodes, tonsils, and appendix.

Susumu Tonagawa and Immunity

Introduce students to the important contributions Japanese immunologist Susumu Tonagawa has made toward our understanding of the immune system. Tonagawa was able to show that somatic cells use a multi-step process to rearrange fragments from different genes, in different ways, to produce many different antibodies, proving that individuals inherit only a small number of genes that diversify in specialized somatic cells. For this work, Tonagawa received a Nobel prize in 1987.
Interferon is produced by a body cell that has been infected by the virus. The interferon diffuses to uninfected neighboring cells, which then produce antiviral proteins that can prevent the virus from multiplying.

**Acquired Immunity**

The cells of your innate immune system continually survey your body for foreign invaders. When a pathogen is detected, these cells begin defending your body right away. Meanwhile, as the infection continues, another type of immune response that counteracts the invading pathogen is also mobilized. Certain white blood cells gradually develop the ability to recognize a specific foreign substance. This acquired immune response enables these white blood cells to inactivate or destroy the pathogen. Defending against a specific pathogen by gradually building up a resistance to it is called **acquired immunity**.

Normally, the immune system recognizes components of the body as self, and foreign substances, called antigens, as nonself. Antigens are usually proteins present on the surfaces of whole organisms, such as bacteria, or on parts of organisms, such as the pollen grains of plants. An acquired immune response occurs when the immune system recognizes an antigen and responds to it by producing antibodies against it. Antigens are foreign substances that stimulate an immune response, and antibodies are proteins in the blood that correspond specifically to each antigen. The development of acquired immunity is the job of the lymphatic system. The process of acquiring immunity to a specific disease can take days or weeks.

**The lymphatic system**

Your lymphatic (lihm FA tihk) system not only helps the body defend itself against disease, but also maintains homeostasis by keeping body fluids at a constant level.

**MiniLab 39.2**

**Observe and Infer**

**Distinguishing Blood Cells** The human immune system includes five types of white blood cells in the bloodstream: basophils, neutrophils, monocytes, eosinophils, and lymphocytes.

**Procedure**

1. Copy the data table below.
2. Mount a prepared slide of blood cells on the microscope and focus on low power. Turn to high power and look for white blood cells. **CAUTION:** Use care when working with microscope slides.
3. Find a neutrophil, monocyte, eosinophil, and lymphocyte. You may see a basophil, although they are rare. Refer to Figure 39.9 for photos of these cells.
4. Count a total of 50 white blood cells, and record how many of each type you see.
5. Calculate the percentage by multiplying the number of each cell type by two. Record the percentages. Diagram each cell type.

**Type of White Blood Cell** | **Number Counted** | **Percent** | **Diagram**
--- | --- | --- | ---
Neutrophil | | | |
Monocyte | | | |
Basophil | | | |
Lymphocyte | | | |
Eosinophil | | | |

**Analysis**

1. **Summarize** Which type of white blood cell was most common? Second most common?
2. **Describe** How do red and white blood cells differ?

**Expected Results**

The common percentages of white blood cells are: neutrophils, 60–70%; lymphocytes, 20–25%; monocytes, 3–8%; eosinophils, 2–4%; and basophils, 0.5–1%.

**Analysis**

1. neutrophils, lymphocytes
2. White blood cells have a nucleus; red blood cells don’t.

**Modified Assessment**

**Knowledge** Quiz students by having them identify unlabeled photos of the different types of white blood cells. L1

**Research** Have students who need an additional challenge research the difference between the two main groups into which white blood cells are categorized. Granulocytes include neutrophils, basophils, and eosinophils. They contain large granules in their cytoplasm that are visible under a light microscope after staining has occurred. Agranulocytes include monocytes and macrophages. Although these cells contain granules, they are not visible under a light microscope after staining. L3
Figure 39.10 shows the major glands and vessels that make up the lymphatic system. Your body's cells are constantly bathed with fluid. This tissue fluid is composed of water and dissolved substances that diffuse from the blood into the spaces between the cells that make up the surrounding tissues. This tissue fluid collects in open-ended lymph capillaries. Once the tissue fluid enters the lymph vessels, it is called lymph.

Lymph capillaries meet to form larger vessels called lymph veins. The flow of lymph is only toward the heart, so there are no lymph arteries. The lymph veins converge to form two major lymph ducts. These ducts return the lymph to the bloodstream in the shoulder area, after it has been filtered through various lymph glands.

Describe how lymph is circulated through the body.

Glands of the lymphatic system

At locations along the lymphatic system, the lymph vessels pass through lymph nodes. A lymph node is a small mass of tissue that contains lymphocytes and filters pathogens from the lymph, as shown in Figure 39.11. Lymph nodes are made of an interlaced network of connective tissue fibers that hold lymphocytes. A lymphocyte (LIHM fuh site) is a type of white blood cell that defends the body against foreign substances.

The tonsils are large clusters of lymph tissue located at the back of the mouth cavity and at the back of the throat. They form a protective ring around the openings of the nasal and oral cavities. Tonsils provide protection against bacteria and other pathogens that enter your nose and mouth.

The spleen is an organ that stores certain types of lymphocytes. It also filters out and destroys bacteria and worn-out red blood cells, and acts as a blood reservoir. Unlike lymph nodes, the spleen does not filter lymph.

Another important component of the lymphatic system is the thymus gland, which is located above the heart. The thymus gland stores immature lymphocytes until they mature and are released into the body's defense system.
Antibody Immunity

Acquired immunity involves the production of two kinds of immune responses: antibody immunity and cellular immunity. Antibody immunity is a type of chemical warfare within your body that involves several types of cells. Follow the steps of antibody immunity illustrated in Figure 39.12.

When a pathogen invades your body, it is first attacked by the cells of your innate immune system, as shown in Figure 39.12A, B, and C. If the infection is not controlled, then your body builds up acquired immunity to the antigen by producing antibodies to it. A type of lymphocyte called a T cell becomes involved. A T cell is a lymphocyte that is produced in bone marrow and processed in the thymus gland. Two kinds of T cells play different roles in immunity.

One kind of T cell, called a helper T cell, interacts with B cells, shown in Figure 39.12D, E, and F. A B cell is a lymphocyte that, when activated by a T cell, becomes a plasma cell and produces antibodies. B cells are produced in the bone marrow. Plasma cells, shown in Figure 39.12G and H, release antibodies into the bloodstream and tissue spaces. Some activated B cells do not become plasma cells but remain in the bloodstream as memory B cells. Memory B cells are ready and armed to respond rapidly if the same pathogen invades the body at a later time. The response to a second invasion is immediate and rapid, usually without any symptoms.

**Figure 39.12**

Antibody immunity utilizes B cells and antibodies in defending your body against invading pathogens.

**Visual Learning**

Figure 39.12 Ask students to write a summary of what is happening in this figure.

**Reinforcement**

Compare the antigen-antibody reaction to the lock-and-key fit of enzymes and substrates.

**Concept Development**

Explain to students that normally the body’s immune response helps maintain homeostasis. However, sometimes the body loses its ability to discriminate between self and nonself, which leads to autoimmunity.

Autoimmunity is a response by antibodies or sensitized T cells against a person’s own tissue antigens. It is involved in multiple sclerosis, Graves’ disease of the thyroid, rheumatic fever (in which antibodies are formed against the heart), and juvenile diabetes (in which antibodies are formed against the pancreas).
Cellular Immunity

Like antibody immunity, cellular immunity also involves T cells with antigens on their surfaces. The T cells involved in cellular immunity are cytotoxic, or killer, T cells. T cells stored in the lymph nodes, spleen, and tonsils transform into cytotoxic T cells that are specific for a single antigen. However, unlike B cells, they do not form antibodies. Cytotoxic T cells differentiate and produce identical clones. They travel to the infection site and release enzymes directly into the pathogens, causing them to lyse and die. The steps in cellular immunity are illustrated in Figure 39.13.

The same cells that protect the body against pathogens can sometimes cause problems within the body. Sometimes the immune system overreacts to a harmless substance such as pollen. Mast cells release histamines in large amounts, causing the symptoms of an allergic reaction: sneezing, increased mucus production in the nasal passages, and redness. The immune system also can recognize its own cells as foreign and mistakenly attack the body’s own tissues in what is referred to as an autoimmune disorder, such as lupus or rheumatoid arthritis. T cells and antibodies also can attack transplanted tissue, such as a transplanted kidney, that comes from a source outside the body.

Passive and Active Immunity

Acquired immunity to a disease may be either passive or active. Passive acquired immunity develops as a result of acquiring antibodies that are generated in another host. For example, prior to birth and during nursing, a human infant acquires passive immunity to disease from its mother.
Active acquired immunity develops when your body is directly exposed to antigens and produces antibodies in response to those antigens.

Passive immunity involves acquiring antibodies produced in someone else, such as through an injection or a mother passing them through the placenta to her fetus. Active immunity is due to a person forming his or her own antibodies after being exposed to an antigen.

Passive immunity may develop in two ways. Natural passive immunity develops when antibodies are transferred from a mother to her unborn baby through the placenta or to a newborn infant through the mother’s milk. Artificial passive immunity involves injecting into the body antibodies that come from an animal or a human who is already immune to the disease. For example, a person who is bitten by a snake might be injected with antibodies from a horse that is immune to the snake venom.

Active immunity

Active immunity is obtained naturally when a person is exposed to antigens. The body produces antibodies that correspond specifically to these antigens. Once the person recovers from the infection, he or she will usually be immune if exposed to the pathogen again.

Active immunity can be induced artificially by vaccines. A vaccine is a substance consisting of weakened, dead, or incomplete portions of pathogens or antigens that, when injected into the body, cause an immune response. Vaccines produce immunity because they prompt the body to react as if it were naturally infected. Table 39.2 lists some common vaccines.

In the late 1790s, Edward Jenner, an English country doctor shown in Figure 39.14, demonstrated the first safe vaccination procedure. Jenner knew that dairy workers who acquired cowpox from infected cows were resistant to catching smallpox during epidemics. Cowpox is a disease similar to, but milder than, smallpox. To test whether immunity to cowpox also caused immunity to smallpox, Jenner infected a young boy with cowpox. The boy developed a mild cowpox infection. Six weeks later, Jenner scratched the skin of the boy with viruses from a smallpox victim.

Active immunity can be induced artificially by vaccines. A vaccine is a substance consisting of weakened, dead, or incomplete portions of pathogens or antigens that, when injected into the body, cause an immune response. Vaccines produce immunity because they prompt the body to react as if it were naturally infected. Table 39.2 lists some common vaccines.

In the late 1790s, Edward Jenner, an English country doctor shown in Figure 39.14, demonstrated the first safe vaccination procedure. Jenner knew that dairy workers who acquired cowpox from infected cows were resistant to catching smallpox during epidemics. Cowpox is a disease similar to, but milder than, smallpox. To test whether immunity to cowpox also caused immunity to smallpox, Jenner infected a young boy with cowpox. The boy developed a mild cowpox infection. Six weeks later, Jenner scratched the skin of the boy with viruses from a smallpox victim.

This portrait shows Jenner vaccinating a young boy against smallpox. A worldwide attack on the disease through vaccinations brought an end to it. Because of the efforts of the World Health Organization, smallpox has been eliminated.
The viruses for cowpox and smallpox are so similar that the immune system cannot tell them apart. The boy, therefore, did not get sick because he had artificially acquired active immunity to the disease. To learn more about how vaccines work, try the Problem-Solving Lab on this page.

AIDS and the Immune System

In 1981, an unusual cluster of cases of a rare pneumonia caused by a protozoan appeared in the San Francisco area. Medical investigators soon related the appearance of this disease with the incidence of a rare form of skin cancer called Kaposi’s sarcoma. Both diseases seemed associated with a general lack of function of the body’s immune system.

By 1983, the pathogen causing this immune system disease had been identified as a retrovirus, now known as Human Immunodeficiency (ih myew noh dih FIIH shun see) Virus, or HIV. HIV kills helper T cells and leads to the disorder known as Acquired Immune Deficiency Syndrome, or AIDS.

HIV is transmitted when blood or body fluids from an infected person are passed to another person through direct contact, or through contact with objects that have been contaminated by infected blood or other body fluids. Methods of transmission include intimate sexual contact, contaminated intravenous needles, and blood-to-blood contact, such as through transfusions of contaminated blood.

Since 1985, careful screening measures have been instituted by blood banks in the United States to help keep HIV-infected blood from being given to people who need transfusions. A pregnant woman infected with the virus can transmit it to her fetus. The virus can also be transmitted through breast milk.

Abstinence from intimate sexual contact provides protection from HIV and other sexually transmitted diseases. Among illegal drug users, HIV transmission can be prevented by not sharing needles.
The HIV virus in Figure 39.15 is basically two copies of RNA wrapped in proteins, then further wrapped in a lipid coat. The knoblike outer proteins of the virus attach to a receptor on a helper T cell. The virus can then penetrate the cell, where it may remain inactive for months. HIV contains the enzyme reverse transcriptase, which allows the virus to use its RNA to synthesize viral DNA in the host cell.

The first symptoms of AIDS may not appear for eight to ten years after initial HIV infection. During this time, the virus reproduces and infects an increasing number of T cells. Infected persons may eventually develop AIDS. During the early stages of the disease, symptoms may include swollen lymph nodes, a loss of appetite and weight, fever, rashes, night sweats, and fatigue.

It is not known what percentage of persons infected with HIV will develop AIDS, but the majority of those untreated will. In most cases, as AIDS progresses, infectious diseases or certain forms of cancer take advantage of the body’s weakened immune system and homeostasis is severely disrupted.

Understanding Main Ideas
1. Identify the structures of and interpret the functions of the immune system.
2. Explain the difference between innate immunity and acquired immune responses.
3. What role do phagocytes play in defending the body against disease?
4. What role does a lymph node play in defending your body against microorganisms?

Thinking Critically
5. Why is it adaptive for memory cells to remain in the immune system after an invasion by pathogens?
6. Get the Big Picture Sequence the events that occur in the formation of antibody and cellular immunity. For more help, refer to Get the Big Picture in the Skill Handbook.

Extension
Ask students to find out the current status of an AIDS vaccine. Have them look in the latest issues of medical and scientific journals.

Skill Have students explain how the AIDS virus overcomes both nonspecific and specific immunity.
Before You Begin
Emerging diseases are those in which the incidence in humans has increased within the past 20 years or threatens to increase in the near future. These diseases may be new or a mutation of an existing organism, or may be an already identified disease that has spread to a new geographic area or population. Re-emerging diseases are ones that have increased in incidence after a time of decline. Disease agencies are constantly monitoring our world for these types of diseases.

Problem
How can you obtain current research information on emerging and re-emerging diseases?

Objectives
In this BioLab, you will:
- Choose five emerging and five re-emerging diseases for study.
- Collect data on the ten diseases and record in a table.

Materials
access to the Internet

Skill Handbook
If you need help with this lab, refer to the Skill Handbook.

PROCEDURE

1. Copy the two data tables on the next page.
2. Go to eabdl.glencoe.com/internet_lab to find links that will provide you with information for this BioLab.
3. Choose five emerging and five re-emerging diseases you wish to investigate.
4. List the diseases in your data tables and fill in the rest of the columns.
5. Be sure to complete the last two rows of your data table that ask for current research findings and your sources of information.

Teaching Strategies
- You may wish to have students complete all or part of this activity at home if they have access to computers, or in the school library or computer center.
- Point out to students that their data tables will have to be expanded in size to accommodate all the information they obtain.
- Have students share their findings with classmates at the conclusion of the activity.

Data and Observations
Student data and observations will vary, depending on the diseases selected and the information resources used.
**ANALYZE AND CONCLUDE**

1. **Define** What is a pathogen? Provide several examples.

2. **Contrast** Describe the difference between an emerging and a re-emerging disease. Provide several examples of each.

3. **Think Critically** Hypothesize why a disease that was once on the decline might re-emerge.

4. **Apply Concepts** Compared with travel in the 1800s, how would current worldwide travel affect the transmission of disease?

5. **Use the Internet** What are some advantages and disadvantages of getting information on disease research by way of the Internet rather than from textbooks or an encyclopedia?

**Share Your Data**

**Interpret Data** Find this BioLab using the link below, and post your data in the data table provided for this activity. Using the additional data from other students on the Internet, analyze the data and complete your data tables.

**Share Your Data**

To navigate the Internet BioLab, go to [ca.bdol.glencoe.com/internet_lab](ca.bdol.glencoe.com/internet_lab). Ask students to research current efforts to develop a cure for cancer or other diseases.

**Assessment**

**Skill** Have students combine their lists of diseases so that a total of at least 20 diseases are included. Have students use the list to compare characteristics of viral versus bacterial diseases. Use the Performance Task Assessment List for Analyzing the Data in PASC, p. 99.
Purpose
Students will examine the pros and cons of destroying the remaining smallpox cultures.

Teaching Strategies
■ Before reading the feature, have students review Section 39.1 and the role of viruses as causative agents of disease.
■ If possible, arrange for a representative from the local health department to visit the class. Ask the representative to discuss vaccines in general. Have students prepare questions beforehand.
■ After students have read the feature, have volunteers take turns listing on the chalkboard the advantages and disadvantages of destroying smallpox cultures.
■ Make sure students understand the meaning of “bioterrorism.”

The Centers for Disease Control and Prevention offers free information about bioterrorism and U.S. response plans.

Forming Your Opinion
Engage students in a class discussion on the limits of science. Point out that knowledge is the goal of science. However, science cannot answer ethical questions, such as those presented in the article. Have students brainstorm other ethical issues that arise in science, such as using animals for laboratory research. Then allow students to debate the smallpox issue. Encourage them to use scientific explanations in their arguments and to respect others’ opinions.

Destroy or Preserve? The Debate over Smallpox

In 1980, the World Health Organization (WHO) announced an amazing victory in the field of health care—the first disease, smallpox, had been eradicated from the human population. Throughout history, this virus has killed an estimated 500 million people. Smallpox cultures still exist in two laboratories—one in the United States and the other in Russia. Now scientists must decide: Should these cultures be destroyed or preserved?

Smallpox is a highly contagious disease that infects internal organs and can cause blindness, disfigurement, and in 30 percent of cases, death. The only natural reservoir for the virus that causes smallpox is the human body. Smallpox was the first disease for which an effective vaccine was developed. Although vaccination offers protection, the United States and other developed countries stopped their smallpox vaccination programs decades ago. As a result, many people are not protected against the deadly disease. Destroying the virus would seemingly ensure that no one would ever again be infected by smallpox.

The anti-smallpox argument Proponents of destroying the cultures raise additional points. They note that the DNA sequence of the virus has been mapped. This should allow scientists to “reconstruct” the virus in the event that unknown reserves exist either in the natural environment or in other labs. The smallpox virus itself is not used in the vaccine. Some people feel these dangerous cultures should not be kept because it increases the risk that they may accidentally—or worse, deliberately—be let loose on the world.

The pro-smallpox argument Those in favor of preserving the smallpox cultures counter that no one can be absolutely certain that the virus has indeed been contained in only two laboratories. Other hidden cultures may exist. If so, destroying the known cultures will not necessarily protect the world against a smallpox outbreak. In addition, some scientists argue that a DNA map of the virus is insufficient for study purposes. In their opinion, it is crucial to study the virus intact because that is the best way to learn about—and develop strategies against—devastating diseases that attack the human body.

Perspectives The World Health Organization recognizes the complexity of the debate. WHO is made up of global representatives who, among other tasks, offer recommendations about health-care issues that affect the world at large. Since 1986, WHO has consistently stated that the smallpox cultures should be destroyed. However, fear of bioterrorism has risen steadily since that time. In 2002, WHO reversed its stance. Now, the organization says that the remaining cultures should be preserved until new vaccines or other treatments against smallpox are developed. This will also give scientists more time to study the virus.

Think Critically Review the arguments for and against the complete destruction of the smallpox virus. What ethical issues are involved? In your view, should the smallpox virus be destroyed or preserved? Organize a classroom debate about the issue.

To find out more about the debate over smallpox, visit ca.bdel.glencoe.com/biology_society

Going Further
Have students research the history of smallpox. Where and when did the greatest outbreaks occur? Tell students to make graphs that illustrate major epidemics of the disease. Afterwards, discuss how science benefited society by helping to eradicate the virus.
**Section 39.1**

**The Nature of Disease**

**Key Concepts**

- Infectious diseases are caused by the presence of pathogens in the body.
- The cause of an infection can be established by following Koch’s postulates.
- Animals, including humans, and nonliving objects can serve as reservoirs of pathogens. Pathogens can be transmitted by direct contact, by a contaminated object, through the air, or by a vector.
- Symptoms of a disease are caused by direct damage to cells or by toxins produced by the pathogen.
- Some diseases occur periodically, whereas others are endemic. Occasionally, a disease reaches epidemic proportions.
- Some infectious diseases can be treated with antibiotics, but pathogens may become resistant to these drugs.

**Section 39.2**

**Defense Against Infectious Diseases**

**Key Concepts**

- Innate immunity provides general protection against various pathogens.
- Innate immunity includes the physical barrier of the skin as well as mucus, lysozymes in sweat, oil, tears, and saliva, the inflammation response, phagocytosis, and interferons.
- Acquired immunity provides a way of fighting specific pathogens by recognizing invaders as nonself. It includes antibody and cellular immunity.
- The lymphatic system consists of the lymphatic vessels and the lymphatic organs: lymph nodes, tonsils, spleen, and thymus.
- Passive immunity develops as a result of acquiring antibodies generated in another host. Active acquired immunity develops when the body is directly exposed to antigens and produces antibodies in response.

**Foldables™**

Have students use their Foldables to review the content of Section 39.1.
**Vocabulary Review**

Review the Chapter 39 vocabulary words listed in the Study Guide on page 1045. Determine if each statement is true or false. If false, replace the underlined word with the correct vocabulary word.

1. An antibiotic is a disease-causing agent such as a bacterium or a virus.
2. A disease that is constantly present in a population is called an epidemic.
3. Defending against a specific pathogen by gradually building up a resistance to it is called innate immunity.
4. A T cell is a lymphocyte that is produced in the thymus gland.

**Understanding Key Concepts**

5. Any disease caused by the presence of pathogens in the body is called a(n) ________.
   A. infectious disease  
   B. endemic disease  
   C. epidemic disease  
   D. harmless disease

6. Which of the following is NOT an example of transmission of a disease by a vector?
   A.________  
   B.________  
   C.________  
   D.________

7. ________ is a body response to an injury, characterized by redness, swelling, pain, and heat.
   A. Inflammation  
   B. Fever  
   C. Sweating  
   D. Headache

8. A person is given an injection that contains antibodies against the hepatitis A virus. This is an example of which type of immunity?
   A. natural passive immunity  
   B. artificial passive immunity  
   C. natural active immunity  
   D. artificial active immunity

9. Complete the concept map by using the following vocabulary terms: infectious disease, endemic, Koch's postulates, epidemic.

   - When constantly in a population is called an epidemic.
   - 1. ________  
   - 2. ________  
   - 3. ________  
   - 4. ________

   10. The normal flora help keep harmful bacteria and other microorganisms from growing on or within the body. The normal flora of the intestinal tract also secrete some B vitamins. Bacteria that invade body tissues can set up a disease process by killing cells and secreting toxins, upsetting homeostasis.

11. Diseases, whether caused by pathogens, genetics, malnutrition, or chemicals, upset the natural balance of body function. Diseases upset chemical processes, cellular function, and may cause cell death. One example is the pathogen that causes tetanus, which secretes a toxin that affects nerve cell function and can result in uncontrollable muscle contractions, paralysis, and death.

12. The mother’s antibodies to chicken pox crossed the placenta and are in the baby’s blood, protecting the baby against chicken pox.

**Thinking Critically**

13. Infer Why would it be helpful to an infected person’s survival to receive an injection of blood serum from someone who has survived the same disease?

14. **Real World Biochallenge** Visit ca.bdol.glencoe.com to research past episodes in which biological agents for warfare or terrorism have been used. What type of bioterrorism threats is the world currently preparing for? Give a multimedia presentation about your results to your class.

15. The experiment would be a repeat of some of Koch’s postulates, which would include isolating the organism from the parakeets and exposing the organisms to human cell cultures to show the susceptibility of the organisms to humans.

16. If a person were unable to produce B or T cells, he or she would not have specific immunity. The person would not likely be able to survive an infection, especially by a virus.
15. **Design an Experiment**  Several weeks after buying a new pet parakeet, Johann became ill with flu-like symptoms. When he visited the pet store again, many of the parakeets were ill. Design an experiment that would determine if Johann had the same disease as the birds.

16. **Infer**  Some hereditary disorders result in a person being unable to produce B cells or T cells. What effects would this have on a person’s immunity? How would this affect the body overall?

17. When a pathogen enters the body, which cells usually are the first to attack it?
   A. macrophages  
   B. T cells  
   C. B cells  
   D. plasma cells

18. Which of the above cells are responsible for antibody production?
   A. macrophages  
   B. T cells  
   C. B cells  
   D. plasma cells

19. Which of the following cells are destroyed in an AIDS infection?
   A. macrophages  
   B. helper T cells  
   C. B cells  
   D. memory B cells

Study the graph and answer questions 20–22.

21. How many more cases of polio were reported in the year 1980 than in the year 2000?
   A. 100  
   B. 50  
   C. 9  
   D. 0

22. **Open Ended**  Children in the United States began to get vaccinated against polio in 1954. A second type of polio vaccine began to be used in 1963. Explain how vaccines provide immunity against disease. What could account for the cases of polio still occurring after the use of the vaccines?

23. **Open Ended**  If the bacterium that causes tetanus is easily killed by penicillin, why doesn’t penicillin cure the disease tetanus?
Prepare

Short on Time?
This BioDigest can be used as an introduction to or as an overview of the structures and functions of the human body systems. If time is limited, you may wish to use this unit summary to teach about human biology in place of the chapters in the human body unit.

Key Concepts
Students learn about the level of organization in body systems. They are then introduced to the structures and functions of the major body systems. Various vital statistics provide students with interesting facts about the body systems.

1 Focus

Bellringer
Using a large picture of a human body or a plastic model of a torso, ask students to name as many body systems as they can. Have students list organs under each body system. L2 ELL

The Human Body

How do the human body systems function together? When an Olympic ice-skater performs on the ice, the cells, tissues, organs, and organ systems of the skater’s body function together to help the athlete perform at his or her best and perhaps win a gold medal. All body systems must work together to make an award-winning performance possible.

Levels of Organization
All organisms are made of cells. In complex organisms, such as humans, most cells are organized into functional units called tissues. The four basic tissues of the human body are epithelium, muscle, connective, and nervous tissues. Epithelium covers the body and lines organs, vessels, and body cavities. Muscle tissue is contractile and is found attached to bones and in the walls of organs, such as the heart. Connective tissue is widely distributed throughout the body. It produces blood and provides support, binding, and storage. Nervous tissue transmits impulses that coordinate, regulate, and integrate body systems.

Tissues to Systems
Groups of tissues that perform specialized functions are called organs. Your stomach and eyes are examples of organs. Most organs contain all four basic tissue types. Each of the body’s organs is part of an organ system. An organ system contains a group of organs that work together to carry out a major life function. The major organ systems of the human body are described in this BioDigest.

Student Recording Sheet, p. 249
**Skin**

The skin and its associated structures, including hair, nails, sweat glands, and oil glands, are important in maintaining homeostasis in the body. The skin protects tissues and organs, helps regulate body temperature, produces vitamin D, and contains sensory receptors.

**Skeletal System**

The skeletal system consists of the axial skeleton and appendicular skeleton. The axial skeleton supports the head and includes the skull and the bones of the back and chest. The appendicular skeleton contains the bones associated with the limbs. The entire skeleton, which is made up of 206 bones, has many functions. It provides support for the softer, underlying tissues; provides a place for muscle attachment; protects vital organs; manufactures blood cells; and serves as a storehouse for calcium and phosphorus.

**Joints: Where Bones Meet**

The place where two bones meet is called a joint. Joints can be immovable, such as the joints in the skull, or movable, such as the shoulder joints. The shoulder joint is called a ball-and-socket joint; the elbow joint is a hinge joint. The wrists have gliding joints, and the neck has pivot joints.

---

**Visual Learning**

Draw students’ attention to the levels of organization diagram showing how cells are organized into tissues, organs, and organ systems. All systems together make up an organism.

**Concept Development**

Have students examine areas of their skin. The palms of the hands and soles of the feet contain no hairs. The fingertips contain large numbers of sensory nerve endings and ridges to help grip objects. Have students also note the different patterns and types of skin coloration.

**Display**

Have students prepare a bulletin board or posters using pictures cut out of magazines to illustrate the body systems.

---

**The Human Body: Kinesthetic**

A model human skeleton can be used to talk about the skeletal system and how skeletal muscles function. A model of a human torso can be used to demonstrate other body systems. Have students, in groups of two, quiz each other to identify the different bones of the skeletal system. Remove individual organs from the torso model and have students identify the organ, its function, and to which organ system it belongs.
Muscular System

The muscular system includes three types of muscles: smooth, cardiac, and skeletal.

Smooth Muscle

Smooth muscles are found in the walls of hollow internal organs, such as inside the stomach or blood vessels. These muscles are not under conscious control and are called involuntary muscles. Smooth muscle contracts to exert pressure on the space inside the tube or organ it surrounds in order to move material through it.

Skeletal Muscle

Skeletal muscles are usually attached to bones and allow body movement. They can be controlled by conscious effort so they are called voluntary muscles. Skeletal muscle tissue is made up of long, threadlike cells, called fibers, which have alternating dark and light striations. Each fiber has many nuclei.

Heart Muscle

Cardiac muscle tissue is found only in the heart. These cells contain a single nucleus and have striations made up of organized protein filaments that are involved in contraction of the muscle. Like smooth muscle, cardiac muscle is involuntary muscle. Cardiac muscle has the unique ability to contract without first being stimulated by nervous tissue.

VITAL STATISTICS

Muscles

Most powerful skeletal muscle: The muscle you sit on is the gluteus maximus; it moves the thighbone away from the body and straightens the hip joint.

Longest muscle: The sartorius muscle runs from the waist to the knee and flexes the hip and knee.

A broad smile: A smile uses 17 facial muscles; a frown uses more than 40.

INCLUSION STRATEGIES

Hearing Impaired/Learning Disabled

Have students make flash cards with a body system named on one side of the card and its functions on the other side. Students can use the cards as a study aid.

Pages 1050–1051: Biology/Life Sciences 9g*
Levels of glucose in the blood are maintained all day long by hormones secreted by the pancreas. After a meal, the sugars from the food are transported into the blood, raising the blood glucose level. The sugars are either used immediately for activity or stored in the liver for later use. The pancreas secretes insulin, which helps the body’s cells take up the sugar or convert it to glycogen in the liver for storage.

Between meals, when blood glucose levels go down, the pancreas secretes glucagon. Glucagon causes the glycogen in the liver to be broken down into glucose, which is then released into the bloodstream and made available to the body’s cells. The control of blood sugar levels in the body is an example of a feedback mechanism that is vital for maintaining homeostasis.
The Human Body

**Endocrine System**

The endocrine system controls all of the metabolic activities of body structures. This system includes all of the glands in the body that secrete chemical messengers called hormones. Hormones travel in the bloodstream to target cells, where they alter the metabolism of the target cell. Some of the major endocrine glands include the pituitary, thyroid, parathyroids, adrenals, pancreas, ovaries, and testes.

**Nervous System**

The organs of the nervous system include the brain, spinal cord, nerves, and sensory receptors. These organs contain nerve cells, called neurons, that conduct impulses. Nerve impulses allow the neurons to communicate with each other and with the cells of muscles and glands. Each impulse consists of an electrical charge that travels the length of a neuron’s cell membrane.

Between two neurons there is a small gap called a synapse. When one neuron is stimulated, it releases chemicals called neurotransmitters into the synapse, which stimulates a change in electrical charge in the next neuron. Nerve impulses travel through the body this way, from neuron to neuron.

**Sensory Receptors**

Some nerve cells act as sensory receptors that detect both external and internal stimuli. In response to a stimulus, these neurons carry impulses to the spinal cord and brain. The brain and spinal cord then send impulses to muscles or glands, stimulating them to contract or secrete hormones. This interconnection provides coordination between the nervous system and the endocrine system.

The central nervous system (brain and spinal cord) interprets and acts on information it receives from sensory neurons found throughout the body.
Respiratory System

The organs of the respiratory system exchange gases between blood and the air. During inhalation, oxygen in the air passes into the blood from small air sacs called alveoli in the lungs. Body cells use oxygen to break down glucose to make ATP needed for metabolism.

Carbon dioxide (CO₂) is produced by the breakdown of glucose and is transported to the lungs by the blood. In the lungs, carbon dioxide diffuses out of the blood and into the alveoli. It is forced out of the lungs during exhalation. The major organs of the respiratory system are the nasal cavity, the pharynx, larynx, trachea, bronchi, and lungs.

Visual Learning

Review the process of diffusion using the detailed figure of alveoli. Discuss the diffusion of oxygen out of the alveoli into the blood, and carbon dioxide out of the blood into the alveoli.

Quick Demo

Breathing Rates Have students work in pairs. Have one student count the breathing rate of the other student, and vice versa. Compare individual (anonymous) breathing rates to the average breathing rate of the class. Discuss factors that could affect breathing rates, such as size, activity level when the breath rate is measured, and congestion from a cold or allergies.

Enrichment

Have students choose a disease (infectious or noninfectious) of the respiratory system to research.

Tobacco and Cancer Many representatives of the tobacco industry claim there is no proof that use of tobacco causes cancer. After researching the issue, have students write an essay in their journals on how they would respond to the assertion that tobacco usage does not cause cancer. Students can use the results of their research to hold a class debate on this topic.
**Circulatory System**

The circulatory system includes the heart, blood vessels (arteries, veins, and capillaries), and blood. The muscular heart pumps blood through the blood vessels. The blood carries oxygen from the lungs and nutrients from the digestive tract to all body cells. Blood also carries hormones to their target cells, carbon dioxide back to the lungs, and other waste products to the excretory system.

**Urinary System**

Metabolic waste products are created during the breakdown of amino acids. The urinary system removes these metabolic wastes from the blood, maintains the balance of water and salts in the blood, stores wastes in the form of urine, and transports urine out of the body.

The urinary system filters the blood, collects urine, and excretes urine from the body.

The force created by the constriction of the heart muscle causes blood to circulate through the vessels of the body.

**Enrichment**

Have students research the factors involved in the development of arteriosclerosis and its treatment.

**Reinforcement**

**Interpersonal** Play a body systems password game. Divide students into teams of two. One person on each team gives one-word clues to his or her partner, whose job is to guess the password with as few clues as possible. Each team plays against one other team. Each team works on a separate term and alternates giving clues to their partners. The first team to guess their word gets a point, then both teams go on to another password. Tally scores at the end of the game.

**Enrichment**

Have students research the various treatments for kidney disease, including portable kidney dialysis and kidney transplants.

**Photo Essay** Have students become familiar with the different body systems by asking groups of students to use pictures from medical or health journals to prepare a photo essay representing one body system. They should present their essays to the class with an oral explanation.
Reproductive System

The reproductive system is involved in the production of gametes. The male reproductive system produces and maintains sperm cells and transfers them into the female reproductive tract. The female reproductive system produces and maintains egg cells, receives sperm cells, and supports the development of the fetus.

The male reproductive system

The female reproductive system

Lymphatic System

Fluids leak out of capillaries and bathe body tissues. The lymphatic system transports this tissue fluid back into the bloodstream. The lymphatic system also plays an important role in immunity. As tissue fluids pass through lymphatic vessels and lymph nodes, disease-causing pathogens and other foreign substances are filtered out and destroyed.

Innate immunity involves the action of several types of white blood cells that protect the body against any type of pathogen. Macrophages and neutrophils engulf foreign substances that enter the body. If the infection persists, the lymphatic system becomes involved. The body develops an acquired immune response that defends against the specific pathogen.

Acquired immunity involves helper T cells that pass on chemical information about the pathogen to B cells. B cells produce antibodies that disarm or destroy the invaders. Some B cells remain in the body as memory B cells that recognize the antigens if they ever invade the body again. This process provides the body with acquired natural immunity against disease.

The lymphatic system includes lymph nodes, tonsils, the thymus gland, and spleen. T cells mature in the thymus. The spleen stores both T cells and B cells.

3 Assess

Check for Understanding
Provide groups of students with diagrams of the different human body systems. Have them use colored pencils to shade various organs of particular systems. For example, the components of the circulatory system could be colored red (oxygenated blood) and blue (nonoxygenated blood).

Reteach
Students can be broken into groups that are assigned to summarize the components of each of the body’s systems and present the summaries to the class.

Extension
Ask the school nurse to speak to the class on prevention of disease transmission and vaccination.

Assessment

Knowledge Assign each student one component of a body system. Have students write a description of their assigned component and how it interacts with its body system and the entire organism.

Project

Hormones and the Reproductive System Have students read information on how the endocrine system and reproductive system interact. Students can create a visual representation in the form of a chart or table showing how the endocrine system influences the reproductive system.

Challenge Activity

Health-Care Costs Have students who need an additional challenge research premature infant care costs. They can write a position paper on whether Americans should spend more or less on dramatic lifesaving measures and why.
Part 1 Multiple Choice

1. Which of the following is the correct sequence of increasing complexity when describing the levels of organization in the human body?
   A. organs, cells, tissues, organism, organ systems
   B. cells, organ systems, tissues, organism, organs
   C. cells, tissues, organs, organ systems, organism
   D. tissues, cells, organs, organ systems, organism

2. Place the structures of the human body in order from least to most complex.
   A. osteocyte, bone tissue, osteon system, long bone
   B. osteocyte, osteon system, bone tissue, long bone
   C. long bone, osteon system, bone tissue, osteocyte
   D. long bone, bone tissue, osteon system, osteocyte

3. Which of the following statements is NOT true regarding the skeletal system?
   A. The skeletal system and the circulatory system interrelate because red blood cells, white blood cells, and platelets are produced in red bone marrow.
   B. The skeletal system and the muscular system interrelate because skeletal muscles are attached to bones in order to produce movement of the body.
   C. The skeletal system and the digestive system interrelate because bones release digestive juices that help break down food.
   D. The skeletal system functions to support the entire body and protect vital organs, such as the brain, heart, and lungs.

4. The functions of the digestive system include __________.
   A. digesting food, absorbing nutrients, and eliminating undigested food and other wastes
   B. secreting hormones to control the metabolic activities of the body
   C. producing antibodies in response to antigens present in the body
   D. circulating blood containing oxygen throughout the body

5. Which of the following processes does NOT involve an internal feedback mechanism?
   A. The release of insulin from the pancreas to maintain blood glucose levels.
   B. The release of antidiuretic hormone in response to a reduced concentration of water level in the blood.
   C. The release of calcitonin and parathyroid hormone to maintain proper levels of calcium in the blood.
   D. The release of carbon dioxide from the lungs during breathing.

6. In order for an impulse to be transmitted from one neuron to another, nerve cells release __________ at a synapse.
   A. hemoglobin  C. neurotransmitters
   B. luteinizing hormone  D. antibodies
11. In which structure of the female reproductive system does a human embryo normally develop?
   A. ovary  C. placenta
   B. oviduct  D. uterus

12. Failure of the urinary system to maintain homeostasis in the body could result in all of the following except _______.
   A. high levels of nitrogenous waste products in the blood
   B. not enough nutrients reaching body cells
   C. the pH of the blood being abnormal
   D. irregularities in blood osmotic pressure

13. The lymphatic system performs which of the following functions?
   A. transports tissue fluid back into the bloodstream
   B. carries oxygen and carbon dioxide to and from body cells
   C. controls the metabolic activities of body structures
   D. exchanges gases between blood and the air

14. Which of the following statements regarding B cells is NOT true?
   A. B cells are part of innate immunity.
   B. B cells can form plasma cells that produce antibodies to attack foreign cells that invade the body.
   C. B cells can form memory cells that recognize antigens if they invade the body a second time.
   D. B cells are produced in the spleen.

18. Structures involved in innate immunity include the skin and its secretions—mucus, sweat, tears, and saliva—which offer protection against all foreign invaders regardless of species. Inflammation and phagocytosis of pathogens by macrophages and neutrophils also provide innate immunity against infection. Acquired immunity occurs when the body defends itself against a specific pathogen using antibodies.

For more help evaluating open-ended assessment questions, see the rubric on p. 9T.
